

# Exercise 1

- The file `hiv.csv` contains data on an HIV PCR assay calibration. These are dilutions of ten samples at 15 copy numbers from 25 to 20,000,000.
- In theory, the Ct value (Target in the data set) should be linear in log copy number. Fit the calibration line and look at plots to examine the assumptions of linear regression.
- What is the estimated copy number for an unknown if  $Ct = 25$ ?
- The column QS is the Ct value for an in-tube standard. Consider calibrating  $Ct(\text{Target}) - Ct(\text{Standard})$  instead. Does this work better or not? What is a good criterion?

```
> hiv.lm <- lm(Target ~ log(Nominal),data=hiv)
> summary(hiv.lm)
```

Call:

```
lm(formula = Target ~ log(Nominal), data = hiv)
```

Residuals:

Min	1Q	Median	3Q	Max
-9.7150	-0.4416	-0.1037	0.3057	8.6227

Coefficients:

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	38.930434	0.061413	633.9	<2e-16 ***
log(Nominal)	-1.385832	0.005831	-237.7	<2e-16 ***

---

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 0.8828 on 878 degrees of freedom

Multiple R-squared: 0.9847, Adjusted R-squared: 0.9847

F-statistic: 5.649e+04 on 1 and 878 DF, p-value: < 2.2e-16

```

> anova(hiv.lm)
Analysis of Variance Table

Response: Target
          Df Sum Sq Mean Sq F value    Pr(>F)
log(Nominal)  1  44026   44026   56489 < 2.2e-16 ***
Residuals    878    684         1
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

```

# Calibration Results

- Variance is not constant, being higher at higher Ct levels.
- Adding the standard helps unless copy number is very high (more than 1 million)
- Using the Target ~ regression, a Ct value of 25 corresponds to a log copy number of

$$(25 - 38.93)/(-1.386) = 10.05$$

$$\text{Copy number} = \exp(10.05) = 23,167$$

SD ratio

Target ~

vs

Target – QS ~

Use of standard  
is better when copy  
number > 100  
and less than  
5 million

# Exercise 2

- The file AD-Luminex.csv contains Luminex protein assays for 124 proteins on 104 patients who are either AD (Alzheimer's Disease), OD (other dementia) or NDC (non-demented controls).
- See if the measured levels of ApoE are associated with diagnosis.
- See if the measured levels of IL.1beta are associated with diagnosis.

```
> ad.data <- read.csv("AD-Luminex.csv")
> anova(lm(ApoE ~ Diagnosis,data=ad.data))
```

Analysis of Variance Table

Response: ApoE

	Df	Sum Sq	Mean Sq	F value	Pr(>F)
Diagnosis	2	877.9	438.93	3.3662	0.03844 *
Residuals	101	13169.8	130.39		

---

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

```
> anova(lm(log(ApoE) ~ Diagnosis,data=ad.data))
```

Analysis of Variance Table

Response: log(ApoE)

	Df	Sum Sq	Mean Sq	F value	Pr(>F)
Diagnosis	2	3.1377	1.56885	6.1503	0.003016 **
Residuals	101	25.7636	0.25508		

---

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

```
> anova(lm(IL.1beta ~ Diagnosis,data=ad.data))
```

```
Analysis of Variance Table
```

```
Response: IL.1beta
```

	Df	Sum Sq	Mean Sq	F value	Pr(>F)
Diagnosis	2	15.20	7.5992	1.0918	0.3395
Residuals	101	702.97	6.9601		

```
> anova(lm(log(IL.1beta) ~ Diagnosis,data=ad.data))
```

```
Analysis of Variance Table
```

```
Response: log(IL.1beta)
```

	Df	Sum Sq	Mean Sq	F value	Pr(>F)
Diagnosis	2	1.861	0.93033	2.5717	0.0814 .
Residuals	101	36.538	0.36176		

```
---
```

```
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

# Exercise 3

- Download the 12 Affymetrix arrays from the web site
- Load the arrays into R using `Read.Affy` and construct the RMA expression indices
